1.0 Introduction

Marketing researchers have done a lot of work to find and analyze the success of new product concepts before they are launched. This interest has been fueled most by consumer preference-based techniques such as conjoint analysis and multidimensional scaling (Kohli and Krishnamurti, 1987).

According to Kohli and Krishnamurti (1987), the proposed heuristic significantly outperforms a competing Lagrangian relaxation heuristic when simulating real problems in terms of processing time and best solution approximation. Laptops are designed in a way that can satisfy every desire of the consumers according to their defined set of preferences Shiau et al. (2007). Both laptop designers and users can benefit from a better understanding of these choices and preferences. Shiau et al. (2007)

This report aims to solve the challenge of designing a new laptop by identifying the right features of the product by analysing customers' preferences and deriving the value associated with each attribute to increasing profitability and market share using conjoint analysis and principal component analysis.

2.0 Methodology

Using a ranking survey dataset that includes 132 observations of customers who have ranked the 20 product profiles of the laptop and are planning to buy laptops. The 20 conjoint profiles contain attributes (Brand, Harddrive, RAM, Screensize and Price) with respective levels. The conjoint analysis was carried out to evaluate the relative importance of the attribute and the customer's utility for each level of the attribute. This was done using regression with dummy variables.

The independent variables are the rankings given by each respondent for a particular product profile and the dependent variables are the levels of each attribute which are incorporated using dummy variables. The 20 product profiles were checked for approval by calculating the correlation among attributes and levels.

Further baseline attributes were selected (Brand – Apple, Hard drive – 128, RAM – 2, Screensize – 12.1 and Price - 900) which have predefined values as 0 and these were not included in the regression. Using Tableau, the part worths of each level of the attributes were compared with baselines and ranges were calculated to obtain the relative importance between attributes and levels (Figures 1 and 2). Further, the willingness to pay by a customer was also calculated for each level and attribute to find the relative importance between attributes and levels (Figure 4). The utility scores were also calculated which were later used to calculate the market share using the maximum utility rule and the logit share of preference. The maximum utility rule determines the ratio of the number of customers with the highest utility product and the total number of customers that participated in the analysis and the logit share of preference rule determines a respondent's likelihood of selecting a given product configuration which is proportional to the utility of that configuration in comparison to utilities of all other configurations. These were later visualized using Tableau (Figure 5).

To obtain the perceptions of the attributes and levels of the selected 8 product profiles of laptops currently in the market, principal component analysis (PCA) was performed. PCA is used to transform the variables into a smaller set of variables called principal components which are extracted sequentially with the first principal component containing the most variance of data which is a normalized linear combination of features. The first principal component loading vector that defines the direction of the feature was calculated. Singular value decomposition that transforms correlated variables into a set of uncorrelated variables was also performed. The principal component scores are the projected values in this direction. These principal components and scores were later used to generate a perceptual map using Tableau. Further, the projection variance explained was also calculated to examine the strength of the two principal components.

3. 0 Results and Discussions

3.1 Product Profiles

According to Bradlow (2005), the product profiles should be selected in such a way that each profile contains a subset of the attributes. The 20 product profiles satisfy this condition. Figure 1 shows the selected 20-product profile.

(Wittink et. al, 1990 ; McCullough, 2002) states that a feature-rich product may have more total utility than a low-priced one simply because all the small utility weights of the various product features when summed, exceed the utility weight of the price attribute which can create a bias. (Wittink et. al, 1990; McCullough, 2002; Bradlow, 2005) state that the attribute level therefore should be smaller in nature ideally less than six. This condition is also satisfied by the selected product profiles. Figure 2 shows the calculated correlations between the attributes present in the 20 product profiles. The correlations satisfy the correlation conditions to be appropriate for carrying out conjoint analysis. They should be close to zero to avoid multicollinearity issues while performing regression.

According to Green and Srinivasan (1978), reducing the number of features to a reasonable amount that ensures the estimating techniques are accurate while also adequately accounting for customer preferences is the more challenging and frequently subjective task. The most suitable combination will likely vary depending on the type of product or market, the number of relevant features, the type of respondent, etc (Green and Srinivasan, 1978).

The conjoint analysis attempts to determine the product features and levels that most appeal to customers and capture the largest market share. By comparing the benefits produced by each attribute level and choosing the combination that gives the highest overall benefit, the best combination is found. It can be considered a good choice if the study results show that the synthesis of 20 product profiles generates a high level of overall utility and adequately represents the preferences of the target market (Kohli and Krishnamurti, 1989). It is crucial to

remember that the best combination depends on a specific market and customer preferences, so testing a variety of combinations is recommended. A sensitivity analysis should also be performed to see how reliable the results are.

Figure 3: Part- Worths of attributes and levels

The willingness to pay obtained further demonstrates the relative importance of the attributes and the levels. Using the dummy variable coefficients resulting from regression, a comparison was done with the set baseline levels and interpreted as discussed in the following paragraphs.

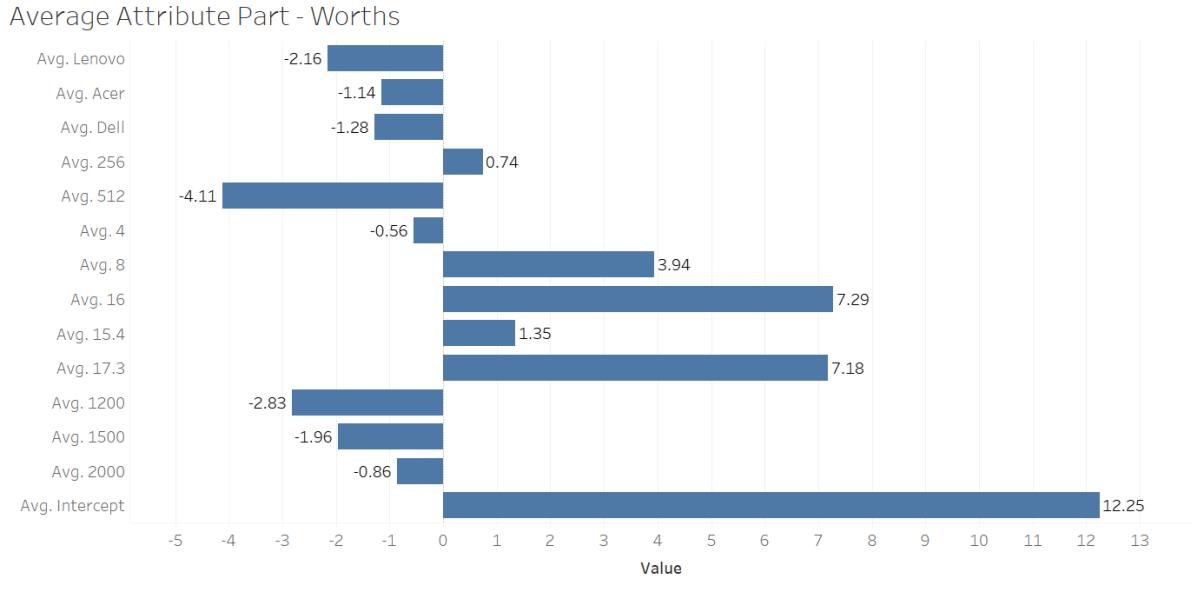

Figure 4: Average Attribute Part-Worths

Figure 4 shows the average value or part worths of the attributes of the laptop. Following the comparison of attributes with the baseline attributes (Apple, 128, 2, 12.1 and 900), it was found that Apple has the highest preference followed by Acer, Dell and Lenovo. In terms of RAM, 16 GB is most valued followed by 8. 4 GB is the least preferred. For screens, 17.3 is the most valued followed by 15.4 and 12.1. In terms of price, 900 is the most valued followed by 2000, 1500 and 1200 by the consumers.

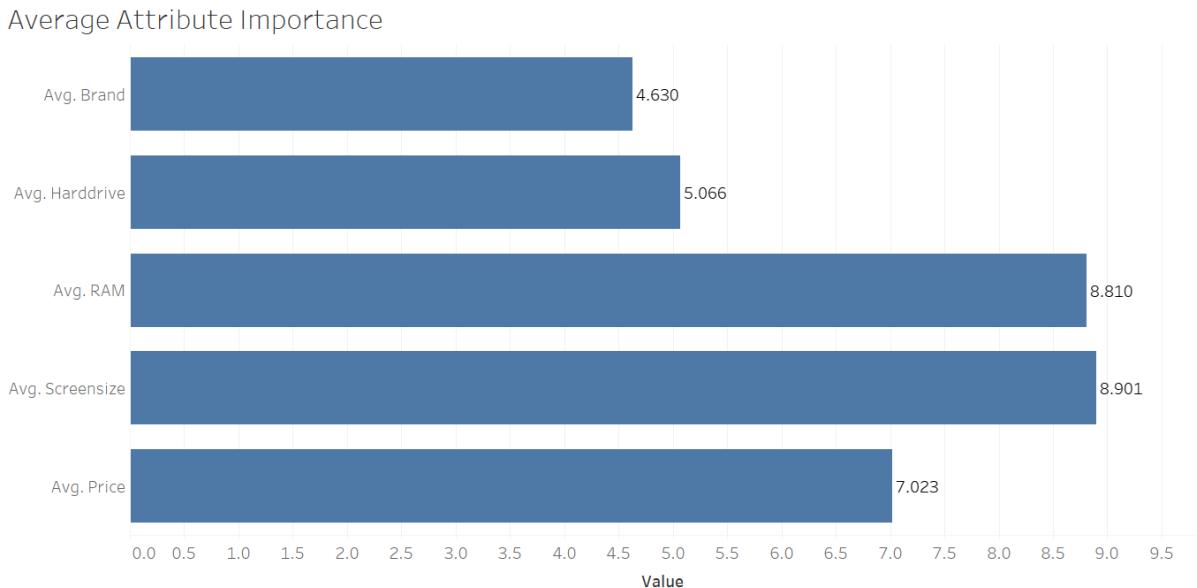

Figure 5: Average Attribute Importance

Figure 5 shows the average importance given by customers to each attribute. Here, the highest importance is given to Screensize (8.901) and the least importance to Brand(4.630). The distribution of percentages of the importance of attributes is shown in Figure 6.

Percentage Average Attribute Importance

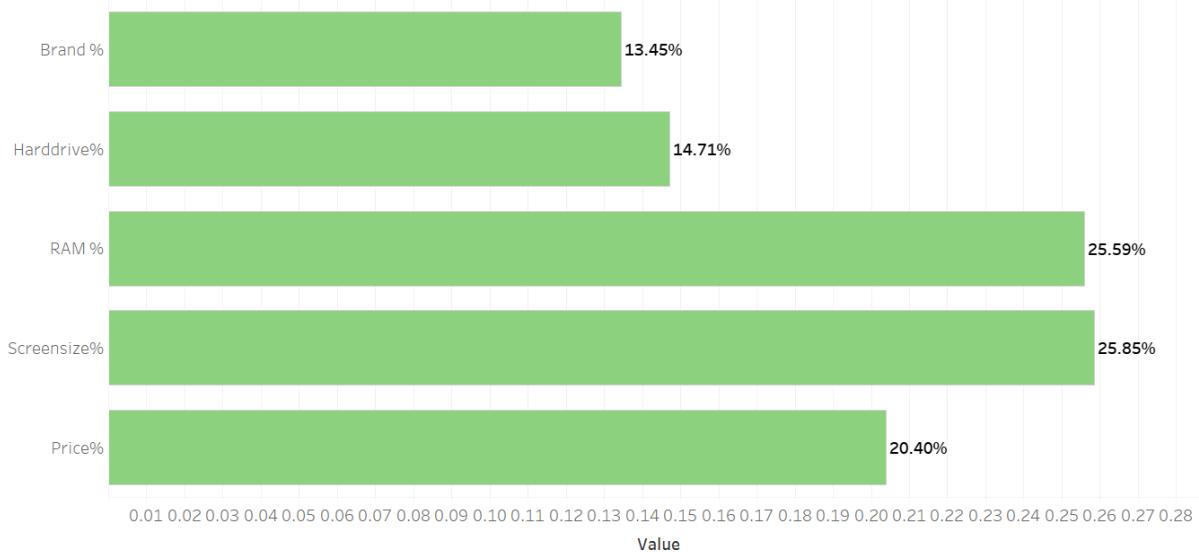

Figure 6: Percentages of Attribute Importance

Average Willingness to Pay for a Feature

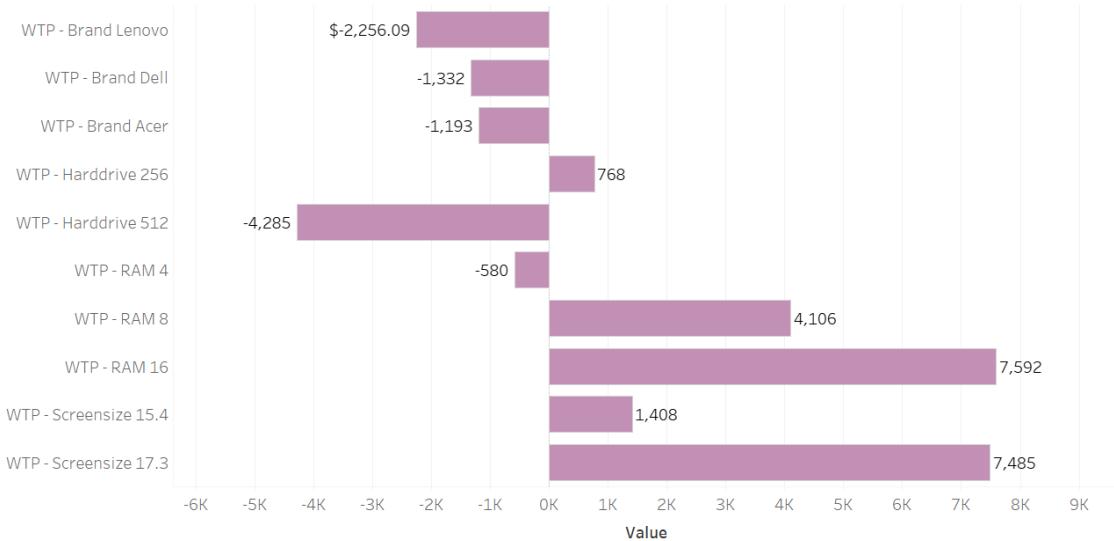

Figure 7: Average Willingness to pay for attributes

Figure 7 shows the average willingness to pay a customer for various attributes of the laptop. According to the distribution, the customer is highly likely to pay for Apple followed by Dell, Acer and Lenovo. For hard drives, 256 GB is the most preferred followed by 128 GB and the least preferred is 512 GB. For RAM, 16 GB RAM is the most preferred followed by 8, 4 and 2 GB. The screen size 17.3 in is the most preferred followed by 15.4 and 12.1 in.

3.2 Distribution of Market Share

Market Share - Current Products

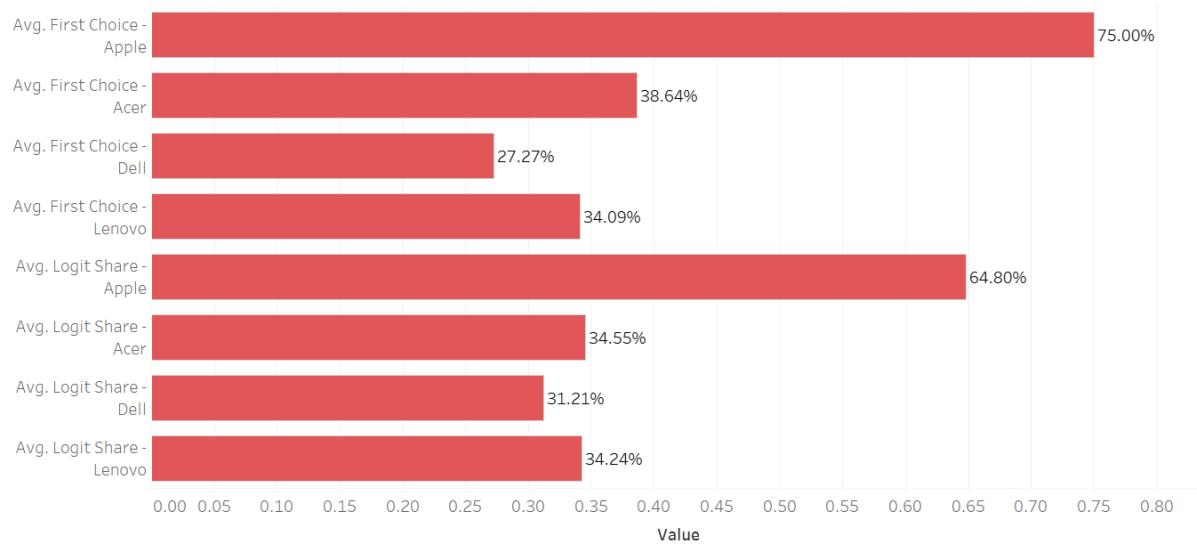

Figure 8: Market Share for current products

Figure 5 shows that the most preferred brand is Apple with a 75 % market share calculated using the maximum utility rule and 64.80% using Logit share. Acer has a slightly higher market share than Lenovo and the least market share is of Dell.

3.3 Perceptual Maps

Perceptual Map of Brands and Attributes

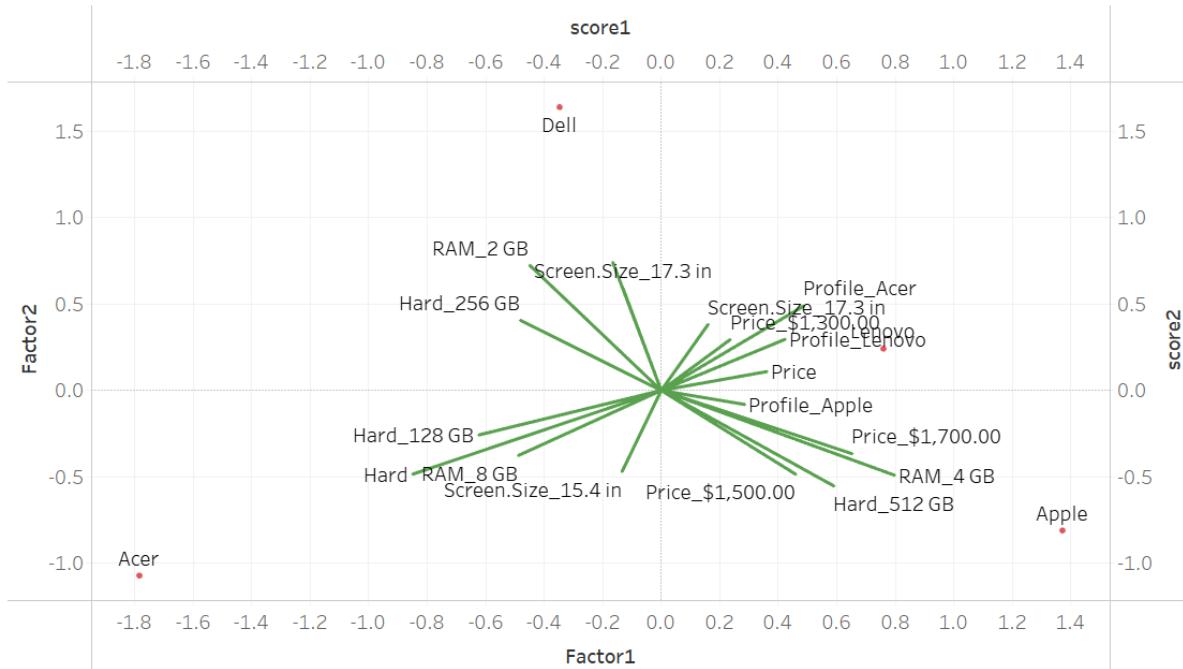

Figure 6: Perceptual Map

Figure 6 shows the perceptual map created using PCA to determine the positioning of the attributes and the brands of the laptop in the market. Factor 1 and Factor 2 are the principal components 1 and 2 respectively. From Figure 6, it can be seen that Apple has performed well in terms of price, hard drives and 4 GB RAM but has performed poorly in screen sizes. However, Acer and Dell perform poorly in terms of the level of prices and perform fairly well in hard drives, screen size and RAMs. Lenovo has performed well in both prices and screen sizes.

3.4 Conjoint Analysis in Market Segmentation

The notion of segmentation can be implemented in different ways, mainly depending on the type of segmentation basis used (Vriensf, 1994). Conjoint methods have been used in several practical marketing research studies since they were first introduced (Rao, 2010). The responsiveness condition is undoubtedly met when segments are created using Partworth utilities (Vriensf, 1994).

Conjoint analysis has been used in the transportation sector. According to Silver (2018), using detailed profiles of service offerings, this technique allows respondents to identify their preferences. The next step examines how the sample population can be partitioned into homogeneous subsets that roughly correspond to market categories (Silver, 2018).

According to Vriensf (1994), some underlying criteria should be followed for performing target segmentation. These include substantiality, accessibility and actionability. The use of benefits beats alternative segmentation bases, as evidenced by the literature, as this foundation is the only one that can meet all of the aforementioned requirements (Wedel, 1990). Conjoint analysis is the most popular method for operationalizing the idea of benefits Vriensf (1994). These benefit segments are formulated in stages that include calculating part – worths and then the segments are created using a clustering algorithm based on the similarity of benefits (Vriensf, 1994). Lopes et. al (2009) state that as conjoint analysis allows researchers to understand the structure of consumer preferences, and cluster analysis allows these customers to be classified according to their preferences, these two together can be very beneficial. Consequently, they further state that segmenting markets based on consumer preferences allows researchers and industry professionals to more accurately assess actual preferences and develop marketing strategies that better match consumers' interests showing enormous potential in the tourism market.

Green and Krieger (1991) state that recent developments such as user-friendly software packages and developments in product line positioning algorithms also pave the way to performing conjoint analysis in market segmentation. However, there are some limitations involved such as errors subject to the parameter estimations. According to Cattin and Wittink (1982), there are difficulties in the interpretation of brand and prices in the conjoint analysis as several other attributes can cover various aspects of the brand name while price can be seen as a product quality indicator which makes it controversial.

5.0 Appendix – R Code

```
## installing and importing packages

install.packages("conjoint")
install.packages("data.table")
library(conjoint)
library(data.table)

set.seed(14)

#### defining attribute levels

attrib.level <- list(brand = c("Apple", "Lenovo", "Dell", "Acer"),
                     Harddrive = c("128", "256", "512"),
                     RAM = c("2", "4", "8","16"),
                     Screensize = c("12.1", "15.4", "17.3"),
                     Price = c("900", "1200", "1500","2000"))
```

The screenshot shows the RStudio interface. The top menu bar includes File, Edit, Code, View, Plots, Session, Build, Debug, Profile, Tools, and Help. The top toolbar has icons for file operations like Open, Save, and Run. The left sidebar shows project files: marassign2.R, conjoint analysis.r, Untitled1*, and perceptual and preference maps.r. The main area has tabs for Source on Save, Go to file/function, and Addins. The code editor tab shows R script code:

```
8
9 set.seed(14)
10
11 ### defining attribute levels
12
13 attrib.level <- list(brand = c("Apple", "Lenovo", "Dell", "Acer"),

The screenshot shows the RStudio interface with the following details:

- File Menu:** File, Edit, Code, View, Plots, Session, Build, Debug, Profile, Tools, Help.
- Project:** Project: (None)
- Code Editor:** The script pane contains R code for reading a CSV file, creating a dummy variable, running PCA, naming the results, and extracting standard deviations. The code is as follows:

```
82 per <- read.csv(title.choose()) ## Choose perceptions.csv title
83 
84 # Create dummy variable
85 per <- dummy_cols(per)
86 per
87 
88 ## Run Principle Components Analysis on Perceptions
89 pca <- prcomp(per[,6:length(per)], retx=TRUE, scale=TRUE)
90 pca
91 names(pca)
92 
93 pca$sdev
```
- Console:** The console pane shows the execution of the R code. It includes the command to read the CSV file and the resulting PCA output.
- Output:** The output pane displays the PCA loadings matrix, which is a table of values ranging from 0 to 1. The columns represent different profiles (Acer, Apple, Dell, Lenovo) and hard drive capacities (512 GB, 8 GB, 16 GB, 2 GB). The rows represent various computer configurations based on profile, RAM, screen size, and price.
- System Tray:** The bottom right corner shows system icons for battery, signal, and date/time (03-05-2023, 14:42).

```

87 ## Run Principle Components Analysis on Perceptions

#####Calculating PVE#####

###https://rpubs.com/cbolch/531355

Create a function that creates a new data frame with centered variables

```
center_apply <- function(x) {
```

```

apply(x, 2, function(y) y - mean(y))

}

##https://rpubs.com/cbolch/531355

# Apply the function

data_centered <- center_apply(per[,6:length(per)])

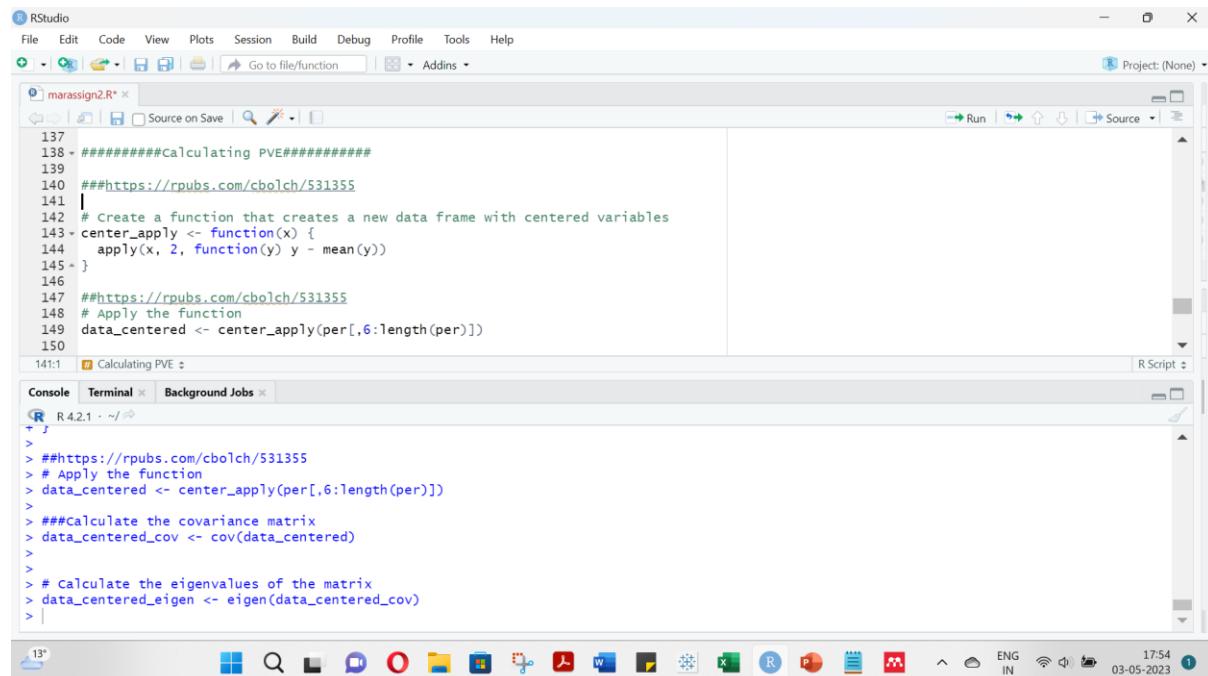

```

```

###Calculate the covariance matrix

data_centered_cov <- cov(data_centered)

```

```

# Calculate the eigenvalues of the matrix

data_centered_eigen <- eigen(data_centered_cov)

```

```

##https://rpubs.com/cbolch/531355

# Structure of the object contains the ordered eigenvalues and the corresponding eigenvector
matrix

str(data_centered_eigen)

```

```

##https://rpubs.com/cbolch/531355
###Selecting the Number of Principal Components
##Proportion of variance explained (PVE)

```

```
PVE <- data_centered_eigen$values / sum(data_centered_eigen$values)
```

```
round(PVE, 2)
```

The screenshot shows the RStudio interface with the following details:

- File Menu:** File, Edit, Code, View, Plots, Session, Build, Debug, Profile, Tools, Help.
- Project:** Project (None).
- Code Editor:** A script named "marassign2.R" containing the R code provided in the text above. Line 160 shows the use of the `str` function on the `data_centered_eigen` object.
- Console:** Shows the output of the R session. It includes the structure of the `data_centered_eigen` object, the calculation of PVE, and the result of rounding it to two decimal places. The output is as follows:

```

#> # Structure of the object contains the ordered eigenvalues and the corresponding eigenvector matrix
#> str(data_centered_eigen)
List of 2
$ values : num [1:20] 1.13 0.845 0.718 0.513 0.378 ...
$ vectors: num [1:20, 1:20] 0.297 -0.301 0.179 -0.176 -0.237 ...
- attr(*, "class")= chr "eigen"

```
- System Status Bar:** Shows the system tray icons, language (ENG IN), battery level (1755), and date/time (03-05-2023).

5.1 Appendix - Tableau

The screenshot shows the Tableau Data Source interface. On the left, the 'Connections' pane lists 'part.worths' as the active connection. The main area displays the 'part.worths.csv' file with 51 fields and 132 rows. A preview table shows data for brands like Apple, Lenovo, Dell, and Acer. The bottom status bar shows system icons and the date/time: 16:34 03-05-2023.

#	part.worths.csv	#	part.worths.csv	#	part.worths.csv	#	part.worths.csv	#	part.worths.csv	#	part.worths.csv
Intercept	20.9530	Apple	0	Lenovo	0.27000	Dell	6.3250	Acer	6.9090		128
